2 Combinatorics

2.1 combinatorics

```
nCr = nC(r-1) * ((n-r+1)/r)
nCr = (n-1)Cr + (n-1)C(r-1)
```

3 Data Structures

3.1 Disjoint Set Union Find

```cpp
///DSU: Path compression + Union by size
```

```cpp
///It turns out, that the final amortized time complexity is
    O((n)), where (n) is the inverse Ackermann function,
    which grows very slowly. In fact it grows so slowly, that
    it doesn't exceed 4 for all reasonable n (approximately
    n<10^600).

int par[10005];
int sz[10005];

int Find(int r) ///Path compression
{
    if( par[r] == r ) return r;
    par[r] = Find(par[r]);
    return par[r];
}

void Union(int a, int b) {  ///Union by size of subtrees.
    a = Find(a);
    b = Find(b);
    if (a != b) {
        if (sz[a] < sz[b]) swap(a, b);
        par[b] = a;
        sz[a] += sz[b];
    }
}

int main()
{
    for( int i = 0; i < 10005; ++i ) {
        par[i] = i;
        sz[i] = 1;
    }
}
```

3.2 mos

```cpp
///mos algorithm
///Complexity: O(sqrt(N) * (N+M))

const int mx = 3e5+5;

const int block_sz = 550;    // N ~ 3e5
int freq[mx], mo_cnt = 0;
int ret[mx];

inline void add(int idx) {
    ++freq[a[idx]];
    if(freq[a[idx]] == 1) ++mo_cnt;
}

inline void del(int idx) {
    --freq[a[idx]];
    if(freq[a[idx]] == 0) --mo_cnt;
}

inline int get_ans() {
```

```cpp
        return mo_cnt;
}

struct queries {
        int l, r, idx;
        queries() { }
        queries(int _l, int _r, int _i) : l(_l), r(_r), idx(_i)
                { }
        bool operator < (const queries &p) const {
                if(l/block_sz != p.l/block_sz) return l < p.l;
                return ((l/block_sz) & 1) ? r > p.r : r < p.r;
        }
};

void mo(vector<queries> &q) {
        sort(q.begin(), q.end());
        memset(ret, -1, sizeof ret);

        // l = 1, r = 0 if 1-indexed array
        int l = 0, r = -1;
        for(auto &qq : q) {
                while(qq.l < l) add(--l);
                while(qq.r > r) add(++r);
                while(qq.l > l) del(l++);
                while(qq.r < r) del(r--);
                ret[qq.idx] = get_ans();
        }
}
```

3.3   sparse table

```cpp
///sparse table
///0-based indexing
//https://cp-algorithms.com/data_structures/sparse-table.html

///1. range sum query (copied from cp-algorithms)

                sp[r2 - (1 << a) + 1][c2 - (1 << b) + 1][a][b]));
}
```

4   Flow

4.1   Dinic with and without scaling

```cpp
/**
Dinic algorithm with scaling and not scaling.
Complexity with scaling : O(VE * lg(U)). here, U is the maximum
        capacity
Complexity without scaling : O((V^2)E)

//////
Complexity in unit graph: O(E*sqrt(V)).
A unit network is a network in which all the edges have unit
        capacity, and for any vertex except s and t either
        incoming or outgoing edge is unique. That's exactly the
        case with the network we build to solve the maximum
        matching problem with flows.
So, Dinic gives similar performance to hopcroft karp algorithm
        incase of maximum bipartite matching as it has the same
        time complexity.
//////
```

```cpp
3rd fastest max flow implementation

1. Works on directed graph
2. Works on undirected graph
3. Works on multi-edge (directed/undirected) graph
4. Works on self-loop(directed/undirected) graph

Can find the actual flow.
Can find the non-maxflow upto a certain value

//////
Implement it on your own. very easy. just a simple O(n) dfs.

Can find minimum cut sets(A and B).
A contains source itself and the nodes that are reachable from
    source using non-saturated edges.
B contains sink and the nodes that are not reachable from
    source using non-saturated edges.
Value of minimum cut capacity is summation of the per_cap of
    all edges u->v such that u belongs to set A, v belongs to
    set B.
Value of minimum cut flow is = (summation of the flow of all
    edges u->v such that u belongs to set A, v belongs to set
    B) - (summation of the flow of all edges v->u such that v
    belongs to set B, u belongs to set A)
Value of minimum cut capacity == maxflow.

To find the minimum cut sets(A and B) first find the maxflow.
    Then, we apply dfs from the source. This dfs will be such
    that- only
the nodes of set A will eventually be marked visited. Suppose
    we have reached in node u, that means u belongs to set A.
    Now,
If (flow of edge u->v) < (per_cap of edge u->v) then v belongs
    to set A.
else if(flow of edge u->v) == (per_cap of edge u->v) then v
    belongs to set B.

To find the minimum cut sets with minimum cardinality, first
    multiply (E+1) with all the edges. Then add 1 to all the
    edges. Then run the maxflow algorithm.
//////

4.4 minCostflow$_{b}y_{d}acin21_{1}$

```cpp
/**
// Push-Relabel implementation of the cost-scaling algorithm
// Runs in O( <max_flow> * log(V * max_edge_cost)) = O( V^3 *
    log(V * C))
// Operates on integers
// Works on regular directed graphs.

// Can't operate on doubles. For this, use bellman
    ford/djikstra method.
//Whether or not it works on undirected or multi-edge or
    self-loop graphs is yet to be verified.

// To get the actual flow collect all the edges which have (f >
    0) - this works just like
    the actual flow finding in normal max flow algorithms;

// Can't find nonMaxflow value upto K. The code is too complex
    for me to add this function.
    Maybe its not possible at all and you can only do it with
        the bellmanFord/Djikstra method.

4.7 Push relabel with gap heuristic and highest labeling

```
/**
Push relabel with gap heuristic and highest labeling
Complexity : O(V^2 * sqrt(E))

2nd fastest max flow implementation

1. Works on directed graph
2. Works on undirected graph
3. Works on multi-edge(directed/undirected) graph
4. Works on self-loop(directed/undirected) graph

Can find the actual flow.

//////
Implement it on your own. very easy. just a simple O(n) dfs.

Can find minimum cut sets(A and B).
A contains source itself and the nodes that are reachable from
    source using non-saturated edges.
B contains sink and the nodes that are not reachable from
    source using non-saturated edges.
Value of minimum cut capacity is summation of the per_cap of
    all edges u->v such that u belongs to set A, v belongs to
    set B.
Value of minimum cut flow is = (summation of the flow of all
    edges u->v such that u belongs to set A, v belongs to set
    B) - (summation of the flow of all edges v->u such that v
```

```
belongs to set B, u belongs to set A)
Value of minimum cut capacity == maxflow.

To find the minimum cut sets(A and B) first find the maxflow.
    Then, we apply dfs from the source. This dfs will be such
    that- only
the nodes of set A will eventually be marked visited. Suppose
    we have reached in node u, that means u belongs to set A.
    Now,
If (flow of edge u->v) < (per_cap of edge u->v) then v belongs
    to set A.
else if(flow of edge u->v) == (per_cap of edge u->v) then v
    belongs to set B.

To find the minimum cut sets with minimum cardinality, first
    multiply (E+1) with all the edges. Then add 1 to all the
    edges. Then run the maxflow algorithm.

```

4.8   Push relabel with gap heuristic and lowest labeling

```
/**
Push relabel with gap heuristic and lowest labeling
Complexity : O(V^2 * sqrt(E))

Not so fast max flow implementation, but is said to work faster
    than highest labeling in very few worst cases(highly
    unlikely).

1. Works on directed graph
2. Works on undirected graph
3. Works on multi-edge(directed/undirected) graph
4. Works on self-loop(directed/undirected) graph

Can find the actual flow.
```

```
Does not work for unsigned types.

//////
Implement it on your own. very easy. just a simple O(n) dfs.

Can find minimum cut sets(A and B).
A contains source itself and the nodes that are reachable from
    source using non-saturated edges.
B contains sink and the nodes that are not reachable from
    source using non-saturated edges.
Value of minimum cut capacity is summation of the per_cap of
    all edges u->v such that u belongs to set A, v belongs to
    set B.
Value of minimum cut flow is = (summation of the flow of all
    edges u->v such that u belongs to set A, v belongs to set
    B) - (summation of the flow of all edges v->u such that v
    belongs to set B, u belongs to set A)
Value of minimum cut capacity == maxflow.

To find the minimum cut sets(A and B) first find the maxflow.
    Then, we apply dfs from the source. This dfs will be such
    that- only
the nodes of set A will eventually be marked visited. Suppose
    we have reached in node u, that means u belongs to set A.
    Now,
If (flow of edge u->v) < (per_cap of edge u->v) then v belongs
    to set A.
else if(flow of edge u->v) == (per_cap of edge u->v) then v
    belongs to set B.

To find the minimum cut sets with minimum cardinality, first
    multiply (E+1) with all the edges. Then add 1 to all the
    edges. Then run the maxflow algorithm.

6   Graph

6.1   2-SAT

```cpp
///2_SAT

///Complexity: O(N)
///https://cp-algorithms.com/graph/2SAT.html
```

```cpp
///While practicing, its better to revise the concept of 2SAT
    from cp-algorithms and steven halim.
/**
    1. p xor q == (p or q) and (not_p or not_q)
       not_(p xor q) == (not_p or q) and (p or not_q)

    2. For any or relation (p or b) we will add directed
       edges:-
       not_p -> b, not_b -> p

    3. The node for x is 2*x. Node for not_x is 2*x+1.

    4. If any node x and its inverse not_x is in same SCC
       then the problem is not 2-satisfiable. Otherwise
       it is.

    5. To find the actual assignment-
       any node x will be given true if its component is
           situated to the left of the component of its
           inverse not_x- in the topological ordering.
**/

///After making the implication graph, if the graph is
    undirected, then instead of using the SCC method we can
    directly use the DSU method to find the strongly
    connected components which is a little bit simpler, and
    helps to solve faster in some problems. (in undirected
    graphs, if two nodes are in same component then they are
    said to be strongly connected)

int nds; ///no. of nodes (x and not_x). we will use [2,nds] for
    denoting nodes.

        if (!visited[i]) dfs(i);
    }
}
```

6.3 dsu on trees

```
//https://codeforces.com/blog/entry/44351
```

Hi!

Most of the people know about dsu but what is the "dsu on tree"?

In Iran, we call this technique "Guni" (the word means "sack" in English), instead of "dsu on tree".

I will explain it and post ends with several problems in CF that can be solved by this technique.

What is the dsu on tree?
With dsu on tree we can answer queries of this type:

How many vertices in the subtree of vertex v has some property in time (for all of the queries)?

For example:

Given a tree, every vertex has color. Query is how many vertices in subtree of vertex v are colored with color c?

Let's see how we can solve this problem and similar problems.

First, we have to calculate the size of the subtree of every vertice. It can be done with simple dfs:

```
int sz[maxn];
void getsz(int v, int p){
    sz[v] = 1; // every vertex has itself in its subtree
    for(auto u : g[v])
        if(u != p){
            getsz(u, v);
            sz[v] += sz[u]; // add size of child u to its
                parent(v)
        }
}
```

Now we have the size of the subtree of vertex v in sz[v].

The naive method for solving that problem is this code(that works in O(N ^ 2) time)

```
int cnt[maxn];
void add(int v, int p, int x){
    cnt[ col[v] ] += x;
    for(auto u: g[v])
        if(u != p)
            add(u, v, x)
}
void dfs(int v, int p){
    add(v, p, 1);
    //now cnt[c] is the number of vertices in subtree of vertex
        v that has color c. You can answer the queries easily.
    add(v, p, -1);
    for(auto u : g[v])
        if(u != p)
```

```
            dfs(u, v);
}
```
Now, how to improve it? There are several styles of coding for
    this technique.

1. easy to code but .
```
map<int, int> *cnt[maxn];
void dfs(int v, int p){
    int mx = -1, bigChild = -1;
    for(auto u : g[v])
        if(u != p){
            dfs(u, v);
            if(sz[u] > mx)
                mx = sz[u], bigChild = u;
        }
    if(bigChild != -1)
        cnt[v] = cnt[bigChild];
    else
        cnt[v] = new map<int, int> ();
    (*cnt[v])[ col[v] ] ++;
    for(auto u : g[v])
        if(u != p && u != bigChild){
            for(auto x : *cnt[u])
                (*cnt[v])[x.first] += x.second;
        }
    //now (*cnt[v])[c] is the number of vertices in subtree of
        vertex v that has color c. You can answer the queries
        easily.

}

2. easy to code and .
vector<int> *vec[maxn];
int cnt[maxn];
void dfs(int v, int p, bool keep){
    int mx = -1, bigChild = -1;
    for(auto u : g[v])
        if(u != p && sz[u] > mx)
            mx = sz[u], bigChild = u;
    for(auto u : g[v])
        if(u != p && u != bigChild)
            dfs(u, v, 0);
    if(bigChild != -1)
        dfs(bigChild, v, 1), vec[v] = vec[bigChild];
    else
        vec[v] = new vector<int> ();
    vec[v]->push_back(v);
    cnt[ col[v] ]++;
    for(auto u : g[v])
        if(u != p && u != bigChild)
            for(auto x : *vec[u]){
                cnt[ col[x] ]++;
                vec[v] -> push_back(x);
            }
    //now (*cnt[v])[c] is the number of vertices in subtree of
        vertex v that has color c. You can answer the queries
        easily.
    // note that in this step *vec[v] contains all of the
        subtree of vertex v.
    if(keep == 0)
```

```cpp
        for(auto u : *vec[v])
            cnt[ col[u] ]--;
}

3. heavy-light decomposition style .
int cnt[maxn];
bool big[maxn];
void add(int v, int p, int x){
    cnt[ col[v] ] += x;
    for(auto u: g[v])
        if(u != p && !big[u])
            add(u, v, x);
}
void dfs(int v, int p, bool keep){
    int mx = -1, bigChild = -1;
    for(auto u : g[v])
        if(u != p && sz[u] > mx)
            mx = sz[u], bigChild = u;
    for(auto u : g[v])
        if(u != p && u != bigChild)
            dfs(u, v, 0); // run a dfs on small childs and clear
                them from cnt
    if(bigChild != -1)
        dfs(bigChild, v, 1), big[bigChild] = 1; // bigChild
            marked as big and not cleared from cnt
    add(v, p, 1);
    //now cnt[c] is the number of vertices in subtree of vertex
        v that has color c. You can answer the queries easily.
    if(bigChild != -1)
        big[bigChild] = 0;
    if(keep == 0)
        add(v, p, -1);
}

4. My invented style .
This implementation for "Dsu on tree" technique is new and
    invented by me. This implementation is easier to code
    than others. Let st[v] dfs starting time of vertex v,
    ft[v] be it's finishing time and ver[time] is the vertex
    which it's starting time is equal to time.

int cnt[maxn];
void dfs(int v, int p, bool keep){
    int mx = -1, bigChild = -1;
    for(auto u : g[v])
        if(u != p && sz[u] > mx)
            mx = sz[u], bigChild = u;
    for(auto u : g[v])
        if(u != p && u != bigChild)
            dfs(u, v, 0); // run a dfs on small childs and clear
                them from cnt
    if(bigChild != -1)
        dfs(bigChild, v, 1); // bigChild marked as big and not
            cleared from cnt
    for(auto u : g[v])
        if(u != p && u != bigChild)
            for(int p = st[u]; p < ft[u]; p++)
                cnt[ col[ ver[p] ] ]++;
    cnt[ col[v] ]++;
```

```cpp
    //now cnt[c] is the number of vertices in subtree of vertex
        v that has color c. You can answer the queries easily.
    if(keep == 0)
        for(int p = st[v]; p < ft[v]; p++)
            cnt[ col[ ver[p] ] ]--;
}
```

But why it is ? You know that why dsu has time (for q queries);
    the code uses the same method. Merge smaller to greater.

If you have heard heavy-light decomposition you will see that
    function add will go light edges only, because of this,
    code works in time.

Any problems of this type can be solved with same dfs function
    and just differs in add function.

6.4   euler$_c$$ircuit_a$$nd_p$ath

```
///The implementation for euler circuit and euler path is
    exactly same.
//http://www.graph-magics.com/articles/euler.php
```

```cpp
/**
    1. Path traversing all the edges just once starting
        from one node and ending at that node is euler
        circuit.
    2. If the path does not end at the source node then
        that path is euler path.
**/
```

```cpp
///euler circuit/euler path for undirected graph
/**
    1. The graph must be a single component. So, you have
        to check it.
    2. All the nodes should have even degree. So, check it.
        But if just 2 nodes have odd degree
    then there will an eulerian path only. Choose any of
        these 2 nodes as source node in that case.
**/
multiset<int> gset[10005];   //gset contains the graph info as
    adjacency list
vector<int> circuit;  //contains the path
void eularcircuit_U(int src)
{
    stack<int> curr_path;

    circuit.clear();
    if(gset[src].empty())return;
    int curr_v = src;

    while (1) {
        if (!gset[curr_v].empty()) {
            curr_path.push(curr_v);
            auto it=gset[curr_v].begin();
            int next_v = *it;
            gset[curr_v].erase(gset[curr_v].lower_bound(next_v));
```

```cpp
            gset[next_v].erase(gset[next_v].lower_bound(curr_v
            curr_v = next_v;
        }
        else {
            circuit.push_back(curr_v);
            if(curr_path.empty()) break;
            curr_v = curr_path.top();
            curr_path.pop();
        }
    }

    reverse(circuit.begin(),circuit.end());
}

/// Euler circuit/euler path for directed graph
/**
    1. The graph -if converted to undirected must be a
        single component. So, you have to check it.
    2. in-degree and out-degree of all nodes should be
        equal. So, check it. But if just 2 nodes have
        unequal in-degree
    and out-degree then there will an eulerian path only if
        and only if one these node(source node to be
        exact) have
    out-degree==1+in-degree and the other have
        in-degree==1+out-degree. Choose any of these
    2 nodes as source node in that case.
**/

            }
        }
    }
}
```

8.5   Tonelli-Shanks(for solving quadratic congruence equation)

```cpp
//solves TIMUS 1132
//can't figure out the time complexity, but its fast

/**
for details-
1. https://www.codechef.com/wiki/tutorial-number-theory#
2. https://www.codechef.com/wiki/tutorial-quadratic-equations#
**/
//This function solves quadratic equation modulo prime p;
//returns -1 if there is no possible solution. i.e the
    congruence equation is not valid.
//returns an answer(if exists) as integer less than prime p.
//This algorithm may work for prime power moduli (according to
    wikipedia, but not tested)

//solves x*x == a (mod p);

/**

                                            ***Important
                                            notes***
**For even prime moduli(p = 2):
1. There is exactly 1 solution in range [1,p-1]. But when range
    is not concerned then there are infinite solutions. If a
    solution is x then the other solutions can be defined as
    k*p+x or k*p-x where k is any integer. you can prove it
    by showing that (k*p+x)^2 and x^2 are congruent modulo p
    or (k*p-x)^2 and x^2 are congruent modulo p.

**For odd prime moduli:
1.If the congruence equation is valid then there are always
    exactly 2 solutions in range [1, p-1]. if a solution is
    x(returned by the function) then the other solution is
    p-x. (Exception: if congruence equation is valid and x =
    0 is returned by the function, then p-x = 0. So, even
    though the congruence equation is valid- there are no
    solutions in range [1,p-1]. However, if range is not
    concerned then there are infinitly many solutions.)
2.But, if range is not concerned then there exists infinite
    solution if the congruence equation is valid. If a
    solution is x then the other solutions can be defined as
    k*p+x or k*p-x where k is any integer. you can prove it
    by showing that (k*p+x)^2 and x^2 are congruent modulo p
    or (k*p-x)^2 and x^2 are congruent modulo p.

// Be careful about choosing the boundary

/**
What is Unimodal function?
We are given a function f(x) which is unimodal on an interval
    [l,r]. By unimodal function, we mean one of two behaviors
    of the function:

 1. The function strictly increases first, reaches a maximum
      (at a single point or over an interval), and then
      strictly decreases.

 2. The function strictly decreases first, reaches a minimum,
      and then strictly increases.
**/

/// Ternary search on function f

/**
      This part is an unproven concept. Invented by me. Use
          it at your own risk.

      If the extrema of the unimodal function is a segment
          instead of a point
      then to get the leftmost or rightmost extremum return
          value of the
      function we may consider adding >= instead of > in the
          "if( )" part of
      the code only if necessary.
**/
